Exercise A1 Compute $p(D|T \in \text{Polytree})$ with Bernoulli CPD's

Show how to compute $p(D|T)$ where T is a DGM which is a polytree and $D = \{x_1, ..., x_N\}$ (and x_i is an assignment of values to all variables of T). Assume that all variables are binary and all CPD's Bernoulli.

Solution.

Theorem 0.1. Chain rule

$$p(\bigcap_k x_k) = \prod_k p(\,x_k \big| \bigcap_{j:j<k} x_j\,) \tag{1}$$

Proof. We can extend the rule

$$p(x_i, x_j) = p(\,x_i|x_j\,)p(x_j) \tag{2}$$

since x_i, x_j is just events we might as well have $x_j = \bigcap_{j'} x_{j'}$ which makes the expression look like this

$$p(x_i \cap \left(\bigcap_{j'} x_{j'}\right)) = p(\,x_i \big| \bigcap_{j'} x_{j'}\,)p(\bigcap_{j'} x_{j'}) \tag{3}$$

by tail-recursion on $p(\bigcap_{j'} x_{j'}) = p(x_a \cap \left(\bigcap_{j' \neq a} x_{j'}\right))$ we will exhaust all j' which leaves us with the base-case $p(x_a)$. Writing out the entire trace of the recursion will gives us the wanted expression for $p(\bigcap_k x_k)$. $\qquad\square$

The first goal is to break down $p(D|T)$ into the CPD's for each node

$$p(\,D|T\,) = \phi\left(\{p(\,x_t|\cdot\,)\}_t\right) \tag{4}$$

this gives an explicit expression for the $p(D|T)$.

Since T is a polytree $\subset$ DAG it is always possible to sort the data topologically according to T.[1] We arrange the indices of the data this way so that it will be topologically sorted according to T and even if it's bad practice in math we replace the old indices with the new sorted ones. This results in variables always having the property $i < j \Rightarrow i$ higher up or equally high as j.[2]

Now apply the chain rule

$$p(D|T) = p(\{x_t\}_k|T) = \prod_k p(x_k \big| \{x_j\}_{j:j<k}, T) \tag{5}$$

Next we note that since we have that the data is topologically sorted we know that

$$\left(D \setminus \{x_j\}_{j:j<k} \right) \cap pa(x_k) = \emptyset \tag{6}$$

in other words the parent cannot be at the same or lower topological level. This results in

$$\{x_j\}_{j:j<k} \supset pa(x_k) \tag{7}$$

which basically states that the parents, denoted $pa(\cdot)$, always is at a higher level.

The next step is to use the conditional independence information from T, which is that a r.v. is only dependent on the parents r.v.'s[3], together with the fact (7) in (5) we get

$$p(D|T) = \prod_k p(x_k \big| \{x_j\}_{j:j<k}, T) = \prod_k p(x_k|pa(x_k)) \tag{8}$$

Finally since we only have cpt's[4] f_t[5], we have that

$$x_t \sim Ber(f_t(pa(x_t))) \tag{9}$$

note that if $pa(x_t) = \emptyset$ then f_t will simply define with one row the probability for x_t directly. Now as explicitly written out as possible

$$p(D|T) = \prod_k p(x_k|pa(x_k)) = \prod_k f_k(pa(x_k))^{x_k} (1 - f_k(pa(x_k)))^{1-x_k} \tag{10}$$

$\square$

---

[1] How we sort the data within a topological level doesn't matter.

[2] "higher" in the context of topological sorting means that it is higher up in the sorted DAG that grows downwards.

[3] At least for a completely visible graph.

[4] According to mail correspondence with the teacher.

[5] Since each distribution has only two states and needs to be normalized to 1, this is the same thing as setting $p \in (0,1)$ in a bernoulli

Exercise A2 Marginalize over non-observed variables

Assume instead that each x_i is an assignment to a subset of the variables say O. Show how to marginalize over $V \setminus O$ (i.e., the non-observed variables).

Solution. Firstly note my syntax for concatenating vectors a, b and indexing the concatenation with k looks like this (the order in which they are concatenated will never make any difference):

$$\{a, b\}_k \tag{11}$$

We denote the observed variables with x_v and the hidden with x_h, both are generally vectors. By general marginalization [6] we have the probability of the observed data

$$p(x_v | T) = \sum_{x_{h'} \in \prod\{0,1\}} p(x_v, x_{h'} | T) \tag{12}$$

$\{x_v, x_{h'}\}$ will together define values for all variables in T which gives us completely observed data which in turn makes it possible to use (10). This should not be confused with having the data for x_h in any way, but if we set $x_h = x_{h'}$ we can regard it as "observed".

The probability for the observed variables will become

$$p(x_v | T) = \sum_{x_{h'} \in \prod\{0,1\}} p(x_v, x_{h'} | T) = \sum_{x_{h'}} \prod_k p(\{x_v, x_{h'}\}_k | pa(\{x_v, x_{h'}\}_k)) \tag{13}$$

writing everything explicitly will be really messy but we do it for the sake of completeness:

$$p(x_v | T) = \sum_{x_{h'} \in \prod\{0,1\}} \prod_k f_k \left(pa(\{x_v, x_{h'}\}_k)\right)^{\{x_v, x_{h'}\}_k} \left(1 - f_k \left(pa(\{x_v, x_{h'}\}_k)\right)\right)^{1 - \{x_v, x_{h'}\}_k} \tag{14}$$

$\square$

Exercise 11.3 EM for the mixtures of Bernoullis

- Show that the M step for ML estimation of a mixture of Bernoullis is given by

$$\mu_{kj} = \frac{\sum_i r_{ik} x_{ij}}{\sum_i r_{ik}} \tag{15}$$

- Show that the M step for MAP estimation of a mixture of Bernoullis with a $\beta(\alpha, \beta)$ prior is given by

$$\mu_{kj} = \frac{\left(\sum_i r_{ik} x_{ij}\right) + \alpha - 1}{\left(\sum_i r_{ik}\right) + \alpha + \beta - 2} \tag{16}$$

---

[6] $p(A) = \sum_{b \in \Omega_B} p(A, B = b)$

3

Solution. The M step is to optimize the auxiliary function Q with respect to π, θ'. Q is the expected posterior log-likelihood[7] with respect to the last parameter θ and the observed data D. [8] The expression for this is

$$Q(\theta', \theta) = \mathrm{E}\left[\log \mathcal{L}_{MAP}(\theta')|D, \theta\right] = \mathrm{E}\left[\log\left(\mathcal{L}(\theta')p(\theta')\right)|D, \theta\right] = \quad (17)$$

$$= \mathrm{E}\left[\ell(\theta') + \log p(\theta')|D, \theta\right] = \mathrm{E}\left[\ell(\theta')|D, \theta\right] + \log p(\theta') \quad (18)$$

and to derive this expression we introducing the latent variable z_i which corresponds to the hidden or missing variables which basically is the *r.v.* for how x_i belongs to the class k. [9] We start with MAP and then derive ML by setting a uniform priori.

$$Q(\theta', \theta) = \mathrm{E}\left[\sum_i \log p(x_i, z_i|\theta')\right] + p(\theta') = \quad (19)$$

since E is linear and we can factor on the different classes and the factors become given with the parameters (π_k, θ'_k) of class k:

$$= \sum_i \left[\mathrm{E} \log\left(\prod_k (\pi_k p(x_i|\theta'_k))^{\mathbb{I}(z_i=k)}\right)\right] + \log \prod_k p(\theta'_k) = \quad (20)$$

then log the inner parts and let E operate on the expression

$$= \sum_i \sum_k \left[\mathrm{E}\left[\mathbb{I}(z_i = k)\right] \log\left[p(x_i|\theta'_k)\right]\right] + \sum_k \log p(\theta'_k) = \quad (21)$$

then we have that the expected $\mathrm{E}\left[\mathbb{I}(z_i = k)\right]$ will be $p(z_i = k|x_i, \theta) = r_{ik}$ which is the expected class-belonging of x_i given the previous parameters θ. The log product rule gives us

$$= \sum_i \sum_k r_{ik} \log \pi_k + \sum_i \sum_k \left\{r_{ik} \log p(x_i|\theta'_k)\right\} + \sum_k \log p(\theta'_k) \quad (22)$$

Now since we have that $\sum_{i,k} r_{ik} \log \pi_k \perp \sum_{i,k} \left\{r_{ik} \log p(x_i|\theta'_k)\right\} + \sum_k \log p(\theta'_k)$ we can optimize the parameters π_k and θ'_k separately and only the θ'_k-term is asked for in the exercise which we denote $\ell(\theta'_k)$.

The model parameters in this case is denoted by μ_k which is a vector and in index-notation μ_{kj}. [10]

---

[7]In the book it's actually just log-likelihood, but this will work in the same way instead of using $Q(\theta', \theta) + \log p(\theta')$ without derivation, we will use posterior-Q as Q instead.

[8]It can be shown that Q is so that the new parameters is always better or as good as the last one, but exclude the proof for this since it's not needed by the exercise.

[9]Responsibility $r_{ik} \triangleq p(z_i = k|x_i, \theta)$

[10]Not using Einstein notation for tensor product.

We start with the MAP

$$\hat{\mu}'_k = \underset{\mu'_k}{argmax}\left\{\sum_i \left\{r_{ik}\log p(x_i|\mu'_k)\right\} + \log p(\mu'_k)\right\} \tag{23}$$

which we find by $\frac{\partial \ell(\mu'_k)}{\partial \mu'_k} = 0$, where $p(x_i|\mu'_k) = \prod_j p(x_{ij}|\mu'_{kj})$ is the multivariate Bernoulli[11] distribution for class k. The priori in the same way is $p(\mu'_k) = \prod_j p(\mu'_{kj})$. In our case for MAP this is $\beta(\alpha, \beta) = \frac{\mu'_{kj}{}^{\alpha-1}(1-\mu'_{kj})^{\beta-1}}{B(\alpha,\beta)}$.

$$\frac{\partial(\ell(\mu'_k))}{\partial \mu'_{kj}} = \frac{\partial \sum_i \left\{r_{ik}\log \prod_{j'} p(x_{ij'}|\mu'_{kj'}) \right\} + \log \prod_{j'} p(\mu'_{kj'})}{\partial \mu'_{kj}} = \tag{24}$$

$$= \frac{\partial \sum_{i,j'} \left\{r_{ik}\log p(x_{ij'}|\mu'_{kj'}) \right\} + \sum_{j'} \log p(\mu'_{kj'})}{\partial \mu'_{kj}} = \tag{25}$$

$$= \left\{\frac{\partial \sum_{j\neq j'}(\cdot)}{\partial \mu'_{kj}} = 0\right\} = \frac{\partial \sum_i \left\{r_{ik}\log \left(\mu'_{kj}{}^{x_{ij}}(1-\mu'_{kj})^{(1-x_{ij})}\right)\right\} + \log \frac{\mu'_{kj}{}^{\alpha-1}(1-\mu'_{kj})^{\beta-1}}{B(\alpha,\beta)}}{\partial \mu'_{kj}} = \tag{26}$$

$$= \frac{\partial \sum_i r_{ik}\left(x_{ij}\log \mu'_{kj} + (1-x_{ij})\log(1-\mu'_{kj})\right)}{\partial \mu'_k} + \tag{27}$$

$$+ \frac{\partial(\alpha-1)\log \mu'_{kj} + (\beta-1)\log(1-\mu'_{kj}) - \log B}{\partial \mu'_k} = \tag{28}$$

$$= \frac{(\sum_i r_{ik}x_{ij}) + \alpha - 1}{\mu'_{kj}} - \frac{(\sum_i r_{ik}(1-x_{ij})) + \beta - 1}{1-\mu'_{kj}} = \tag{29}$$

$$= \frac{(1-\mu'_{kj})(\sum_i r_{ik}x_{ij}) - \mu'_{kj}(\sum_i r_{ik}(1-x_{ij}))}{\mu'_{kj}(1-\mu'_{kj})} + \tag{30}$$

$$+ \frac{(1-\mu'_{kj})(\alpha-1) - \mu'_{kj}(\beta-1)}{\mu'_{kj}(1-\mu'_{kj})} = \tag{31}$$

$$= \frac{(\sum_i r_{ik}x_{ij}) - \mu'_{kj}(\sum_i r_{ik}) + (\alpha-1) - \mu'_{kj}(\alpha+\beta-2)}{\mu'_{kj}(1-\mu'_{kj})} \tag{32}$$

and now find the zero of this expression

$$\frac{(\sum_i r_{ik}x_{ij}) - \mu'_{kj}(\sum_i r_{ik}) + (\alpha-1) - \mu'_{kj}(\alpha+\beta-2)}{\mu'_{kj}(1-\mu'_{kj})} = 0 \tag{33}$$

---

[11]Often called multinoulli.

$$\left(\textstyle\sum_i r_{ik} x_{ij}\right) - \mu'_{kj}\left(\textstyle\sum_i r_{ik}\right) + (\alpha - 1) - \mu'_{kj}(\alpha + \beta - 2) = 0 \tag{34}$$

$$\mu'_{kj}\left[\left(\textstyle\sum_i r_{ik}\right) + \alpha + \beta - 2\right] = \left(\textstyle\sum_i r_{ik} x_{ij}\right) + \alpha - 1 \tag{35}$$

$$\mu'_{kj} = \frac{\left(\sum_i r_{ik} x_{ij}\right) + \alpha - 1}{\left(\sum_i r_{ik}\right) + \alpha + \beta - 2} \tag{36}$$

which is the same as the equation (16). $\qquad\square$

By just looking at the expression for $\beta(\cdot)$ we see that

$$\beta(1,1) = U(0,1) \tag{37}$$

and knowing that ML is a MAP with a uniform priori we can just set $\alpha, \beta = 1$ in the derived expression to get the ML.

$$\mu'_{kj} = \frac{\left(\sum_i r_{ik} x_{ij}\right) + 1 - 1}{\left(\sum_i r_{ik}\right) + 1 + 1 - 2} = \frac{\sum_i r_{ik} x_{ij}}{\sum_i r_{ik}} \tag{38}$$

which is the same as the equation (15). $\qquad\square$
